## **PINGO**

https://pingo.scc.kit.edu/345678

# **Recap: Rank-Queries**

- for a bit vector of size n
- blocks of size  $s = \lfloor \frac{\lg n}{2} \rfloor$
- super blocks of size  $s' = s^2 = \Theta(\lg^2 n)$
- information for 0s or 1s enough
  - $\bullet$  rank<sub>1</sub>(i) = i rank<sub>0</sub>(i)
- for all  $\left|\frac{n}{s'}\right|$  super blocks, store number of 0s from beginning of bit vector to end of super-block
- $n/s' \cdot \lg n = O(\frac{n}{\lg n}) = o(n)$  bits of space

- for all  $\left| \frac{n}{n} \right|$  blocks, store number of 0s from beginning of super block to end of block
- $-n/s \cdot \lg s' = O(\frac{n \lg \lg n}{\lg n}) = o(n)$  bits of space
- for all length-s bit vectors, for every position i store number of 0s up to i
- $\mathbf{Q} = 2^{\frac{\lg n}{2}} \cdot s \cdot \lg s = O(\sqrt{n} \lg n \lg \lg n) = o(n)$  bits of space
- $\blacksquare$  query in O(1) time using three subqueries
  - one in super-block
  - one in block
  - one for remaining bitvector smaller than s

# Select in o(n) Space and O(1) Time

- select<sub>0</sub> in a bit vector of size n that contains k zeros
- naive solutions
  - scan bit vector: O(n) time and no space overhead
  - store k solutions in S[1..k] and  $select_0(i) = S[i] \oplus if k \in O(n/lgn)$  this suffice
- better: k/b variable-sized super-blocks  $B_i$ , such that super-block contains  $b = \lg^2 n$  zeros
- $select_0(i) =$  $\sum_{i=0}^{\lfloor i/b\rfloor-1} |B_j| + select_0(B_{\lfloor i/b\rfloor}, j - (\lfloor i/b\rfloor b))$

- storing all possible results for the (prefix) sum
- $O((k \lg n)/b) = o(n)$  bits of space
- select on block depends on size of block
- $|B_{|i/b|}| \ge \lg^4 n$ : store answers naively
  - requires  $O(b \lg n) = O(\lg^3 n)$  bits of space
  - there are at most  $O(n/\lg^4 n)$  such blocks
  - total  $O(n/\lg n) = o(n)$  bits of space
- $|B_{|i/b|}| < \lg^4 n$ : divide super-block into blocks
  - same idea: variable-sized blocks containing  $b' = \sqrt{\lg n}$  zeros
  - (prefix) sum  $O((k \lg \lg n)/b') = o(n)$  bits
  - if size > lg n store all answers
  - if size < lg n store lookup table</p>

## Rank- and Select-Queries on Bit Vectors

## Lemma: Binary Rank- and Select-Queries

Given a bit vector of size n, there exists data structures that can be computed in time O(n) of size o(n) bits that can answer rank and select queries on the bit vector in O(1) time

#### **Preliminaries**

## Definition: Bit Representation

Given a text T over an alphabet of size  $\sigma$ , each character can be represented using  $\lceil \lg \sigma \rceil$  bits.

- the leftmost bit is the most significant bit and
- the rightmost bit is the least significant bit

0	1	2	3	4	5	6	7	
0)	0)	0	0)	(1	(1	(1	7	MSB
0	0	_	_	0	0	_	_	
0)2	1)2	0)2	1)2	0)2	1)2	0)2	1)2	LSB

- for simplicity characters are integers
- bit representation is integer in binary

#### Definition: Bit Prefix

A bit prefix of length *k* are the *k* MSBs of a characters bit representation

# Wavelet Trees [GGV03] (1/2)

#### **Definition: Wavelet Tree**

Given a text T of length n over an alphabet  $\Sigma = [1, \sigma]$ , a wavelet tree is a binary tree, where

- each node represents characters in  $[\ell, r] \subseteq [1, \sigma]$ ,
- if a node represents characters in  $[\ell, r]$ , then its left and right child
- represent characters in  $[\ell, (\ell+r)/2)$  and  $[(\ell+r)/2, r]$
- lacksquare a node is a leaf if  $\ell + 2 \ge r$
- characters are represented using a bit vector
- an entry is 1 if the character is represented in the right child and 0 otherwise

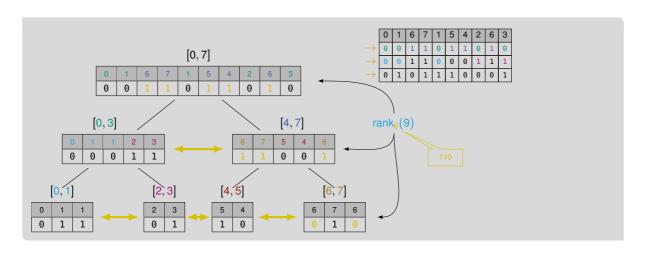

### Definition: Level-wise Wavelet Tree

A wavelet tree, where all bit vectors on the same depth in the tree are concatenated is called level-wise wavelet tree

- in practice, level-wise wavelet trees have less overhead
- navigation still easy

# Wavelet Trees (2/2)

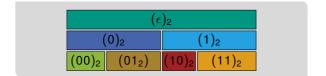

## The Intervals of a Wavelet Tree

- in each node, all represented characters share a bit prefix
- $\blacksquare$  on depth  $\ell$  the longest common bit prefix has length  $\ell-1$
- the bit prefixes form intervals

- finding characters in the wavelet tree requires finding the correct interval
- finding the position of a character requires finding the position in the last interval

# Rank-, Select-, and Access-Queries in Wavelet Trees (1/2)

#### Rank-Queries

- use rank queries on bit vectors
- at depth  $\ell$  as for  $\ell$ -th MSB
- follow through tree according to bit
- as seen on a previous slide
- PINGO what is the query time of rank queries in wavelet trees?

#### **Select-Queries**

- identify leaf containing character
- select corresponding occurrence in leaf
- backtrack position up the tree to the root
- requires up and down traversal of the wavelet tree
- see example on the board

#### **Access-Queries**

- follow bits through the wavelet tree
- return read bits
- same as rank but returning bit pattern instead of final rank
- see example on the board

# Rank-, Select-, and Access-Queries in Wavelet Trees (2/2)

## Lemma: Query Times Wavelet Tree

Given a text T over an alphabet of size  $\sigma$ , the wavelet tree of the text can answer rank, select, and access queries in  $O(\lg \sigma)$  time

## Proof (Sketch)

All queries require

- just a constant number of rank and select queries on the bit vectors and
- at most one traversals from the root of the tree to a leaf and
- one traversal from a leaf to the root of the tree

## **Bit Reversal Permutation**

- lacktriangle given a bit representation of a character  $\alpha$
- $reverse(\alpha)$  reverses the bits
- the MSB becomes the least significant bit

#### **Definition: Bit-Reversal Permutation**

The bit-reversal permutation  $\rho_k$  is a permutation of the numbers  $[0, 2^k)$  with

$$\rho_k(i) = reverse(i)$$

for 
$$i \in [0, 2^k)$$

$$\rho_{k+1} = (2\rho_k(0), \dots, 2\rho_k(2^k - 1), \\ 2\rho_k(0) + 1, \dots, 2\rho_k(2^k - 1) + 1)$$

- same intervals as a wavelet tree
- used in the wavelet matrix

# **Alternative Representation**

- alternative representation of wavelet trees
- removing tree structure
- only two areas per level the intervals discussed before still exist
- better suited for large alphabets
- seemingly less structure
- retaining all important properties

## Definition: Wavelet Matrix [CNP15]

Given a text T of length n over an alphabet of size  $\sigma$  a wavelet matrix consists of

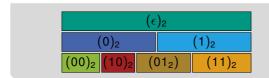

- bit vectors  $BV_{\ell}$  for  $\ell \in [1, \lceil \lg \sigma \rceil]$  of size n and
- an array  $Z[1..\lceil \lg \sigma \rceil]$

#### Such that

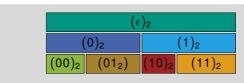

- $lacksquare Z[\ell]$  contains the number of zero bits in  $BV_\ell$
- BV₁ contains all MSBs in text order
- $BV_{\ell}$  contains the  $\ell$ -th MSB the character at position i in  $BV_{\ell-1}$  at position
  - $rank_0(i)$  if  $BV_{\ell-1}=0$  and
  - $Z[\ell-1] + rank_1(i)$  if  $BV_{\ell-1} = 1$

## Intervals of a Wavelet Matrix

- a wavelet matrix has the same intervals a wavelet tree has
- intervals not bounded by parent 1 no tree structure

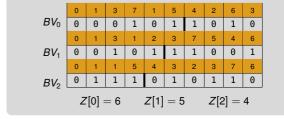

- intervals of a wavelet tree (for comparison)
- **PINGO** is answering queries with a wavelet matrix as simple as with a wavelet tree?

	Θ	1	3	7	1	5	4	2	6	3
$BV_0$	0	0	0	1	0	1	1	0	1	0
	Θ	1	3	1	2	3	7	5	4	6
$BV_1$	0	0	1	0	1	1	1	0	0	1
	Θ	1	1	3	2	3	5	4	7	6
BV <sub>2</sub>	0	1	1	1	0	1	1	0	1	0

- queries on the wavelet matrix work similar
- example on the board <a>=</a>

# Naive Wavelet Tree and Wavelet Matrix Construction (1/2)

	Θ	1	3	7	1	5	4	2	6	3
$BV_0$	0	0	0	1	0	1	1	0	1	0
	Θ	1	3	1	2	3	7	5	4	6
$BV_1$	0	0	1	0	1	1	1	0	0	1
	Θ	1	1	3	2	3	5	4	7	6
$BV_2$	0	1	1	1	0	1	1	0	1	0

				-	-	
$\Lambda \Lambda \Lambda$			$\boldsymbol{\alpha}$		rc	$\sim$
W	a۷	ы	ш		116	:0

- first level are MSBs of characters of text
- for each level  $\ell > 1$ 
  - stably sort text using Radix sort by bit prefixes of length  $\ell-1$

Florian Kurpicz | Text Indexing | 08 Wavelet Trees

- take ℓ-th MSB of sorted sequence
- sorted sequence is new text

	0	1	3	7	1	5	4	2	6	3
$BV_0$	0	0	0	1	0	1	1	0	1	0
	0	1	3	1	2	3	7	5	4	6
$BV_1$	0	0	1	0	1	1	1	0	0	1
	0	1	1	5	4	3	2	3	7	6
BV <sub>2</sub>	0	1	1	1	0	1	0	1	1	0
_	Z	[0]	= 6		<i>Z</i> [1]	= 5		Z[2	2] =	4

#### **Wavelet Matrix**

- first level are MSBs of characters of text
- for each level ℓ > 1
  - stably sort text by ℓ − 1 MSB
  - take ℓ-th MSB of sorted sequence
  - sorted sequence is new text

# Wavelet Tree and Wavelet Matrix Construction (2/2)

to make both fully functional bit vectors are augmented with binary rank and select support

Lemma: Running Time and Memory Requirements Wavelet Tree and Wavelet Matrix

Given a text T over an alphabet of size  $\sigma$ , the wavelet tree and wavelet matrix require  $(1 + o(1))n[\lg \sigma]$  bits of space and can be constructed in  $O(n \lg \sigma)$  time

PINGO is there a asymptotically faster construction method?

- using requires broadword programming
- every  $\tau$ -th level is a big level
- big levels contain enough information to compute small levels below
- small levels computed by splitting big levels
- $O(b/\lg n)$  characters at a time with  $b = o(\lg n)$
- sketch on board <a></a>

#### Lemma: Better Wavelet Tree Construction

Given a text T over an alphabet of size  $\sigma$ , the wavelet tree and wavelet matrix require  $(1 + o(1))n\lceil \lg \sigma \rceil$  bits of space and can be constructed in  $O(n\lg \sigma/\sqrt{\lg n})$  time

can be implemented using AVX/SSE instructions [Din+23; Kan18]

# **Huffman-shaped Wavelet Trees**

- wavelet trees can be compressed
- more precise: the text can be compressed
- use Huffman codes
- wavelet trees cannot handle holes
- use canonical Huffman codes

## Canonical Huffman Codes (Recap)

- start with Huffman codes, code word 0, and length 1
- to get canonical code for current length, then add 1 to code word
- to update length add 1 and append required amount of zeros to code word

## Huffman Codes (Recap)

- idea is to create a binary tree
- $\blacksquare$  each character  $\alpha$  is a leaf and has weight  $Hist[\alpha]$
- create node for two nodes without parent with smallest weight
- give new node total weight of children
- repeat until only one node without parent remains
- label edges:
  - left edge: 0
  - right edge: 1
- path to children gives code for character

# **Huffman-shaped Wavelet Trees**

$\alpha$	$\mathit{hc}(lpha)$	$\mathit{chc}(lpha)$
1	$(11)_2$	(11)2
3	$(01)_2$	$(10)_2$
6	$(100)_2$	$(011)_2$
7	$(101)_2$	$(010)_2$
0	$(0000)_2$	$(0011)_2$
2	$(0001)_2$	$(0010)_2$
4	$(0010)_2$	$(0001)_2$
5	$(0011)_2$	$(0000)_2$

- Huffman codes (hc)
- canonical Huffman codes (chc) that are bit-wise negated

0	1	3	7	1	5	4	2	6	3
0	1	1	0	1	0	0	0	0	1
Θ	7	5	4	2	6	1	3	1	3
0	1	0	0	0	1	1	0	1	0
0	5	4	2	7	6				•
1	0	0	1	0	1				
5	4	0	2						
0	1	1	0						

- intervals are only missing to the right (white space)
- no holes allow for easy querying

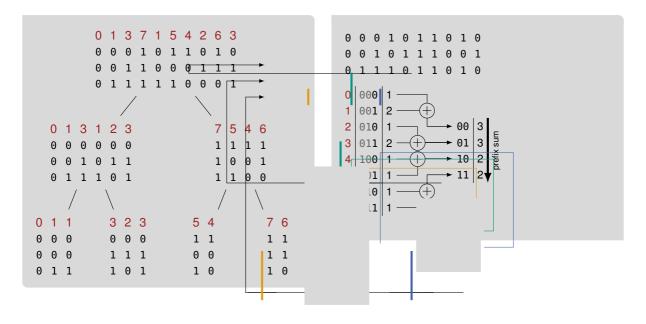

# **Practical Sequential Wavelet Tree Construction**

Florian Kurpicz | Text Indexing | 08 Wavelet Trees

## Bottom-Up Construction [FKL18]

- scan the text and create histogram
- while scanning compute first level
- use histogram to compute borders of intervals
- scan text again and fill bit vectors
- example on the next slide

## **Experimental Setup**

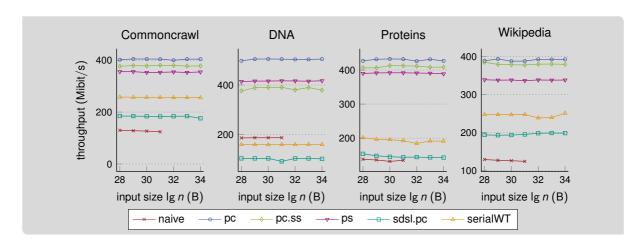

64 GB RAM

Florian Kurpicz | Text Indexing | 08 Wavelet Trees

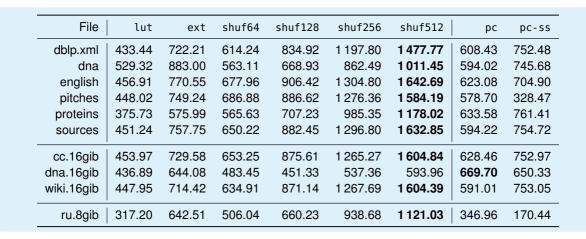

- two Intel Xeon E5-2640v4 CPUs (10 cores at 2.4 GHz base frequency, 3.4 GHz maximum turbo frequency, and cache sizes: 32 KB L1D and L1I, 256 KB L2, 25.6 MB L3)
- same texts as in chapter 04
- results are average of 5 runs

# Experiments: Vectorized Wavelet Tree Construction [Din+23]

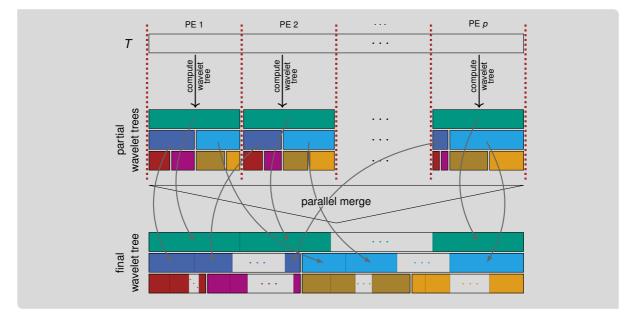

## Parallel Wavelet Tree Construction in Practice

Florian Kurpicz | Text Indexing | 08 Wavelet Trees

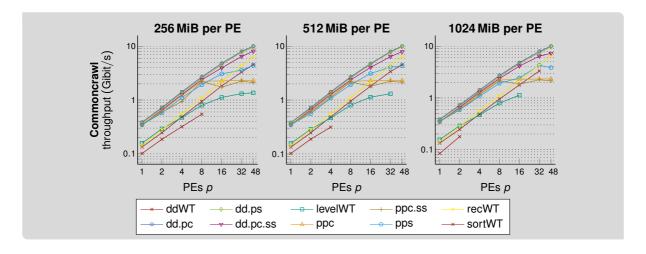

## Domain Decomposition [Fue+17]

- create wavelet tree in parallel using p PEs
- each PE gets a consecutive slice of text
- each PE builds partial wavelet tree for its text
- merge partial wavelet trees in parallel
- can utilize any sequential algorithm
- very fast in practice
- $O(n \lg \sigma / \sqrt{\lg n})$  work and  $O(\sigma + \lg n)$  time [Shu20]

28/29

## **Conclusion and Outlook**

#### This Lecture

- wavelet tree and wavelet matrix
- Huffman-shaped wavelet trees
- select on bit vectors
- practical algorithms for wavelet tree construction
