## 1. What is Randomised Approximation?

## 2. Approximately counting satisfying assignments for Boolean formulas

## Definition

A randomised algorithm  $A$  *approximates* a quantity  $f(x)$  if for any input  $x$  the output  $A(x)$  satisfies:

$$\Pr[|A(x) - f(x)| \leq \varepsilon \cdot f(x)] \geq 1 - \delta.$$

The parameters are the *relative error*  $\varepsilon$  and the *failure probability*  $\delta$ .

## Remark: Related Complexity Classes

PRAS. Problems admitting  $A$  with running time polynomial in  $|x|$ , but not necessarily in  $\frac{1}{\varepsilon}$  (for  $\delta = 1/4$ ).

FPRAS. Problems admitting  $A$  with running time polynomial in  $|x|$  and  $\frac{1}{\varepsilon}$  (for  $\delta = 1/4$ ).

Note: Also defined where  $f(x)$  is not a *number*. For instance: Want to compute a *vertex cover* with a size close to optimal.

# Counting Satisfiable Assignments of Boolean Formulas

## A counting problem

For Boolean formula  $B(x_1, \dots, x_n)$  let  $\#B$  be the number of satisfying assignments:

$$\#B = |\{(x_1, \dots, x_n) \in \{0, 1\}^n \mid B(x_1, \dots, x_n) = 1\}|.$$

## Example

$$B = (x_1 \vee \bar{x}_2) \wedge (\bar{x}_1 \vee x_3)$$

$$\#B = |\{(0, 0, 0), (0, 0, 1), (1, 0, 1), (1, 1, 1)\}| = 4$$

## Approximation algorithm for $\#B$ in general? Unlikely.

Assume  $A$  satisfies  $\Pr[|A(B) - \#B| \leq \varepsilon(\#B)] \leq 1 - \delta$  for  $\varepsilon = \frac{1}{2}$  and  $\delta = \frac{1}{4}$ . Then

$$B \text{ is UNSAT} \Leftrightarrow \#B = 0 \Leftrightarrow \Pr[A(B) = 0] \geq \frac{3}{4}$$

$$B \text{ is SAT} \Leftrightarrow \#B > 0 \Leftrightarrow \Pr[A(B) > 0] \geq \frac{3}{4}$$

If  $A$  is polynomial time then  $A$  is BPP algorithm for SAT.

Then  $\text{SAT} \in \text{BPP}$  and  $\text{NP} \subseteq \text{BPP}$ . Hard to believe...

# What could be a tractable special case?

We must distinguish:  $B$  is UNSAT  $\Leftrightarrow \#B = 0$  from  $B$  is SAT  $\Leftrightarrow \#B \geq 1$ .  
We need not distinguish:  $B$  is TAUT  $\Leftrightarrow \#B = 2^n$  from  $B$  is NON-TAUT  $\Leftrightarrow \#B < 2^n$ .

## CNF is hard on the wrong end

$$(x_1 \vee \bar{x}_2 \vee \bar{x}_{42}) \wedge \dots \wedge (\bar{x}_1 \vee x_3 \vee \bar{x}_{37})$$

Deciding UNSAT is NP-hard.

Deciding TAUT is easy.

$\leftrightarrow$  only empty CNF-formula is TAUT.

## DNF looks good

$$(\bar{x}_1 \wedge x_2 \wedge x_{42}) \vee \dots \vee (x_1 \wedge \bar{x}_3 \wedge x_{37})$$

Deciding UNSAT is easy.

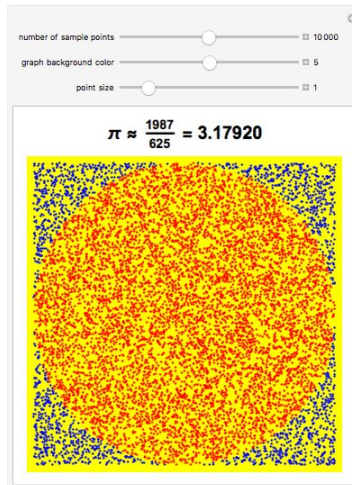

$\leftrightarrow$  only empty DNF-formula is UNSAT.

Deciding TAUT is hard.

Goal: Approximate  $\#B$  for DNF formula  $B$ .

(Equivalently: Approximate  $2^n - \#B$  for CNF formula  $B$ .)

# Intuition: Approximating $\pi$

<https://demonstrations.wolfram.com/ApproximatingPiByTheMonteCarloMethod/>

# Intuition: Approximate $|S|$ for $S \subseteq D$ by sampling from $D$

$$|S| \approx |D| \cdot \frac{0}{16}$$

## Requirements

For this to work we must be able to

- 1 compute the size of  $D$
- 2 sample uniformly from  $D$
- 3 decide for  $x \in D$  whether  $x \in S$

soft requirement:

- 4  $\frac{|S|}{|D|}$  should not be too small

# Approximate $|S|$ for $S \subseteq D$ by sampling from $D$

**Algorithm** approxSetSize:

```

hits ← 0
for i = 1 to N do
  sample x ~ U(D)
  hits ← hits + 1x∈S
return  $\frac{\text{hits}}{N} \cdot |D|$ 
  
```

## Chernoff

For  $\varepsilon \in (0, 1)$  and  $X \sim \text{Bin}(N, p)$ :

$$\Pr[|X - \mathbb{E}[X]| > \varepsilon \mathbb{E}[X]] < 2 \exp(-\varepsilon^2 \mathbb{E}[X]/3).$$

## Simple Theorem

Let  $D$  be a finite set and  $S \subseteq D$  such that we can efficiently

- 1 compute  $|D|$
- 2 sample uniformly from  $D$
- 3 decide for  $x \in D$  whether  $x \in S$

Let  $p = |S|/|D|$ . Then approxSetSize with  $N = \frac{3 \log(2/\delta)}{\varepsilon^2 p}$  approximates  $|S|$  with relative error  $\varepsilon$  and failure probability  $\delta$ .

↪ Special Case  $\varepsilon, \delta = \Theta(1)$ : Need  $N = \Omega(1/p)$  samples.

**Proof:** Apply Chernoff to  $\text{hits} \sim \text{Bin}(N, p)$ .

$$\begin{aligned}
 \Pr[\text{fail}] &= \Pr[|\text{result} - |S|| > \varepsilon |S|] = \Pr\left[\left|\frac{\text{hits}}{N} \cdot |D| - |S|\right| > \varepsilon |S|\right] = \Pr\left[|\text{hits} - \frac{|S|}{|D|} N| > \varepsilon \frac{|S|}{|D|} N\right] \\
 &= \Pr[|\text{hits} - pN| > \varepsilon pN] = \Pr[|\text{hits} - \mathbb{E}[\text{hits}]| > \varepsilon \mathbb{E}[\text{hits}]] \leq 2 \exp(-\varepsilon^2 \mathbb{E}[\text{hits}]/3) = 2 \exp(-\varepsilon^2 pN/3) = \delta.
 \end{aligned}$$

# Approximate $|S|$ for $S \subseteq D$ by sampling from $D$

**Algorithm** approxSetSize:

```
hits ← 0
for i = 1 to N do
  sample x ~ U(D)
  hits ← hits + 1x∈S
return  $\frac{\text{hits}}{N} \cdot |D|$ 
```

## Chernoff

For  $\varepsilon \in (0, 1)$  and  $X \sim \text{Bin}(N, p)$ :

$$\Pr[|X - \mathbb{E}[X]| > \varepsilon \mathbb{E}[X]] < 2 \exp(-\varepsilon^2 \mathbb{E}[X]/3).$$

## Simple Theorem

Let  $D$  be a finite set and  $S \subseteq D$  such that we can efficiently

- 1 compute  $|D|$
- 2 sample uniformly from  $D$
- 3 decide for  $x \in D$  whether  $x \in S$

Let  $p = |S|/|D|$ . Then approxSetSize with  $N = \frac{3 \log(2/\delta)}{\varepsilon^2 p}$  approximates  $|S|$  with relative error  $\varepsilon$  and failure probability  $\delta$ .

↪ Special Case  $\varepsilon, \delta = \Theta(1)$ : Need  $N = \Omega(1/p)$  samples.

## Application to $\#B$

- $S$  = satisfying assignments of  $B$
- $D = \{0, 1\}^n$
- $p = \frac{|S|}{|D|} = \frac{\#B}{2^n}$
- We may have  $p = 1/2^n$
- $N = \Omega(2^n)$  required
- :-)

# No Surprise

Of course this didn't work

Did not exploit that  $B$  is in DNF.

# Approximating $\#B$ for $B$ in DNF

Assume  $B = C_1 \vee \dots \vee C_m$   
 where  $C_i$  contains  $\ell_i$  literals.

- $D_i := \{x \in \{0, 1\}^n \mid C_i(x) = 1\}$  (satisfying assignments of  $C_i$ )
- $D := \{(i, x) \mid i \in [m], x \in D_i\}$  ( $= D_1 \dot{\cup} \dots \dot{\cup} D_m$ )
- $S := \{(i, x) \mid i \in [m], x \in D_i, x \notin D_1 \cup \dots \cup D_{i-1}\}$

**Claim:** We can approximate  $|S| = \#B$  by sampling from  $D$

- 1 We can compute  $|D_i| = 2^{n-\ell_i}$  and  $|D| = \sum_{i=1}^m |D_i|$ . ✓
- 2 We can efficiently sample  $(I, X) \sim \mathcal{U}(D)$  ✓
  - sample  $I$  such that  $\Pr[I = i] = \frac{|D_i|}{|D|}$
  - sample  $X \sim \mathcal{U}(D_i)$ 
    - ↪ set variables appearing in  $C_i$  as required, sample others from  $\text{Ber}(1/2)$ .
  - Yields  $\Pr[(I, X) = (i, x)] = \frac{|D_i|}{|D|} \cdot \frac{1}{|D_i|} = \frac{1}{|D|}$  for all  $(i, x) \in D$ .
- 3 We can efficiently decide “is  $(i, x) \in S$ ?” ✓
  - ↪ just plug  $x$  into all clauses  $C_1, \dots, C_i$  // time  $\mathcal{O}(mn)$
- 4  $p = \frac{|S|}{|D|}$  satisfies  $p \geq \frac{1}{m}$ . ✓

## Theorem

If  $B$  is in DNF, then we can approximate  $\#B$  in polynomial time (using  $N = m \cdot \frac{3 \log(2/\delta)}{\varepsilon^2}$  samples) with relative error  $\varepsilon$  and failure probability  $\delta$ .

## Intuition: Why did this work?

Naive strategy:

Problem:  $|S|/|\{0, 1\}^n|$  may be exponentially small

Improved strategy:

Advantage:  $|S|/|D|$  is  $\Omega(1/m)$ .

## Randomised Approximation is Powerful

For  $B$  in DNF:

- Computing  $\#B$  *exactly* is  $\#\mathbf{P}$ -complete.
- no *deterministic approximation* algorithm for such problems is known
- we analysed an efficient *randomised approximation* algorithm

- Was ist ein randomisierter Approximationsalgorithmus (für ein Zählproblem)?
- Wir haben das Zählproblem  $\#B$  für Boolesche Formeln betrachtet. Hatten wir im allgemeinen Fall Erfolg? Warum nicht?
- Welchen Spezialfall haben wir uns vorgenommen? Wieso tritt dort nicht das selbe Problem auf wie im allgemeinen Fall?
- Wir haben einen Algorithmus gesehen der für zwei Mengen  $S \subseteq D$  die Größe von  $|S|$  schätzt.
  - Unter welchen Annahmen ist dieser anwendbar?
  - Wie hat der Algorithmus funktioniert?
  - Wie hängt die Anzahl der nötigen samples von  $|S|$  und  $|D|$  ab?
- Um  $\#B$  für DNF Formel  $B$  zu schätzen haben wir einen schlaueren Ansatz kennengelernt.
  - Wie hat dieser funktioniert?
  - Wie vermeidet dieser das Problem des naiven Ansatzes?
